A 69-year-old woman with cholestatic liver disease and a low ceruloplasmin level was diagnosed with Wilson's disease based on the presence of Kayser-Fleischer rings, hypercoagulable state, and elevated copper level in serum and liver biopsy specimens. The patient had purplish lesions on the face and hands. The long-term survival of this patient was 11 years. Immunostaining of the liver with a monoclonal antibody against human serum albumin did not show any binding. Two autopsy specimens, a liver and a duodenum, were examined by transmission electron microscopy. Vesicular structures with a uniform thickness and a diameter of 220 nm were found in the hepatocyte canaliculi. These structures were thin walled and well defined. In addition, the proximal sigma duct system contained many thin walled ducts that could be arranged in parallel with flattened cells. One theory is that these thin walled ducts are derived from the proximal sigma duct system.Phishing and the Donor Paradox Posted on May 4, 2012 by Dave Hulme In his book, a classic on the donor paradox, Jack Bales writes: "The paradox of the donor, like the paradox of the criminal, rests upon the assumption that commitment can be made freely and only the actor is responsible for it." Bales goes on to argue that donors don't actually understand or remember the commitments they have made, and that psychological factors may be important in motivating or explaining donor behaviour. Now that donors' consent to donate their organs has been determined in large part by administrative activity, donors are faced with the prospect of discovering and recalling a commitment they made to contribute their organs. 82138339de
